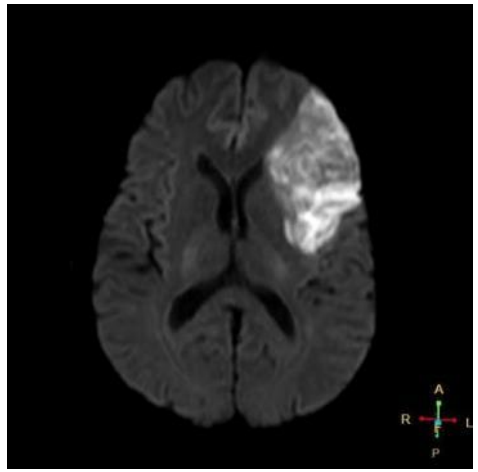
Pharmacology of neurological disease : bridging the translational gap?

Alzheimer's disease

- 75% of neurodegenerative disease cases
- Sporadic form 94%
- 50 million peoples worldwide in 2020
- ≈100 drug failures in clinic phase II-III last 10 years
- 2% success rate (under debate)

Cerebral stroke

- 2nd cause of death worldwide
- 13.7 million cases in 2016
- >1000 molecules reported with protective effects
- >250 clinical trials performed
- 1 drug



CAN WE DO BETTER?

Alzheimer's disease

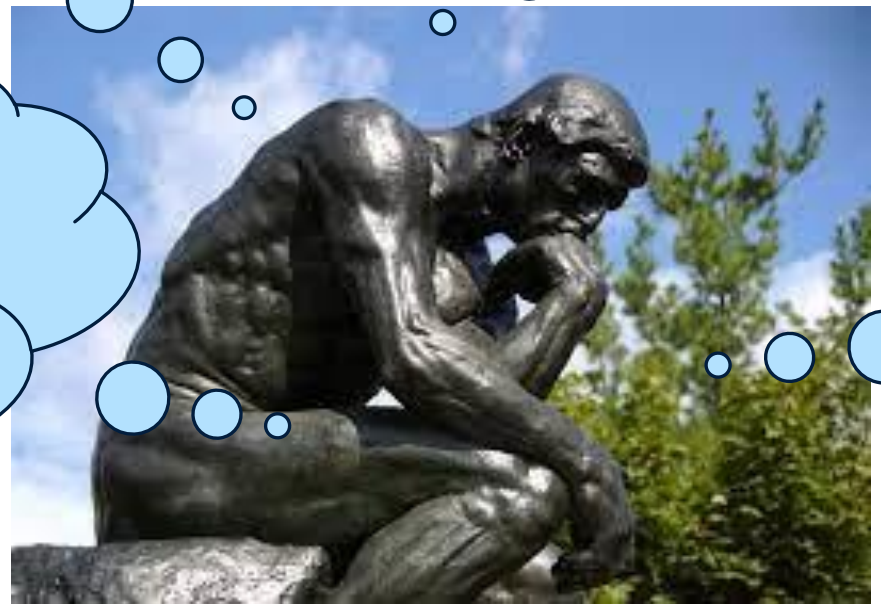
Why animal models are relevant to unravel CNS biology but unpredictive for CNS deseases?

How can we model a pathology that we do not really understand?



Can we do better with NAMs?

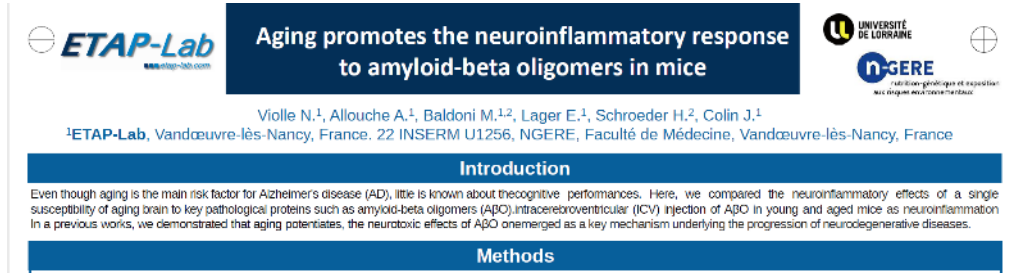
Is using human cells enought and sufficient to improve?

ETAP-Lab
etap-lab.com

Alzheimer's disease

Two strategies at ETAP-Lab:

1. **Refining our animal models**
   - ✓ Wild-type models
   - ✓ Adding risk factors (i.e. age, sex,…)
   - ✓ Respecting chronobiology of the animals



ETAP-Lab

Aging promotes the neuroinflammatory response to amyloid-beta oligomers in mice

UNIVERSITÉ DE LORRAINE

nGERE

Violle N.[1], Allouche A.[1], Baldoni M.[1,2], Lager E.[1], Schroeder H.[2], Colin J.[1]

[1]ETAP-Lab, Vandœuvre-lès-Nancy, France. 22 INSERM U1256, NGERE, Faculté de Médecine, Vandœuvre-lès-Nancy, France

Introduction

Even though aging is the main risk factor for Alzheimer's disease (AD), little is known about thecognitive performances. Here, we compared the neuroinflammatory effects of a single susceptibility of aging brain to key pathological proteins such as amyloid-beta oligomers (AβO).Intracerebroventricular (ICV) injection of AβO in young and aged mice as neuroinflammation In a previous works, we demonstrated that aging potentiates, the neurotoxic effects of AβO onemerged as a key mechanism underlying the progression of neurodegenerative diseases.

Methods

2. **Complexifying our cellular models**
   - ✓ iPSCs with mixed cell types
   - ✓ Using microfluidic systems to model brain connectivity

BIO-DIAMOND

Bio-Diamond project

- **Two partners**
  - **NETRI** => microfluidic devices to create brain-on-chips models
  - **ETAP-Lab** => Alzheimer modeling and drug testing
- The goal is to develop new innovative *in vitro* models of Alzheimer, Parkinson and ALS diseases
- **5 millions €** over 3 years, started in March 2023
- Granted by France 2030

BIO-DIAMOND

NETRI
PROVIDING ORGANS-ON-CHIP FOR THE INDUSTRY

BIO-DIAMOND's Brain-on-Chip

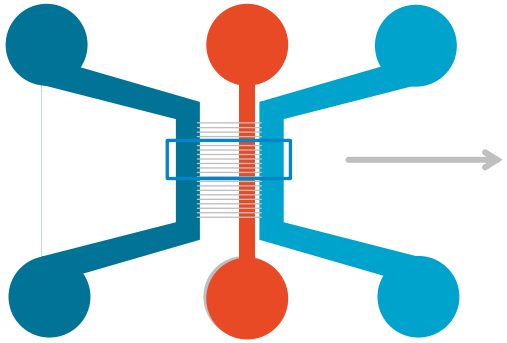
Evaluating the Efficacy of Drug Candidates in Neurodegenerative Diseases

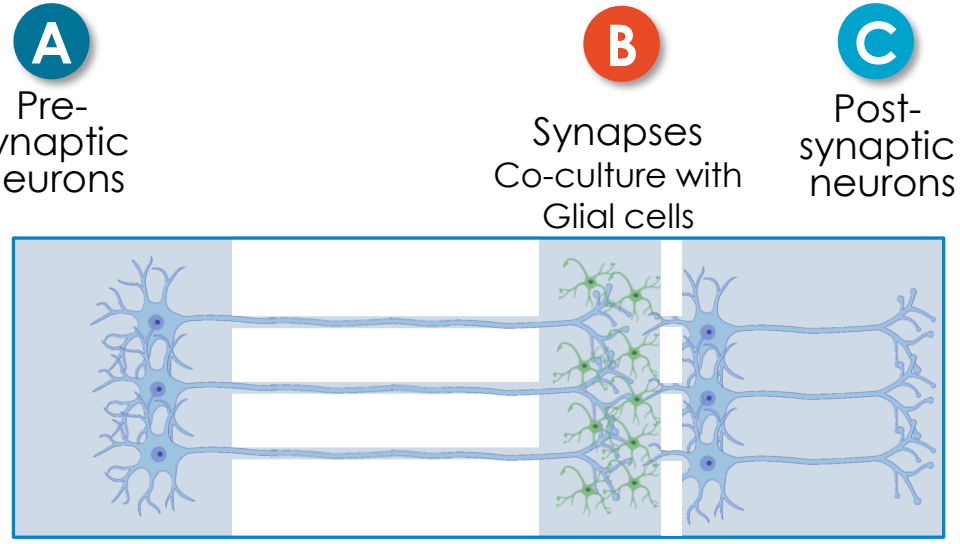
Applications

- Assessment of drug efficacy against neurodegeneration or aggregation / spreading of disease-associated proteins (Aβ, Tau, α-Syn).
- Independent access and manipulation pre- and post-synaptic compartments + synaptic region.

Assay principle

Design of the BoC





NETRI
PROVIDING ORGANS-ON-CHIP FOR THE INDUSTRY

ETAP-Lab
etap-lab.com

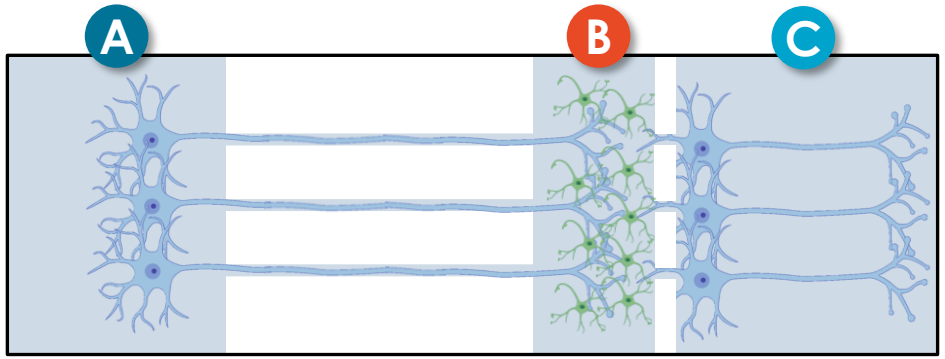
Spreading assay

Goal

Evaluating neurons-to-neurons **spreading** of Tau using microfluidically isolated chambers.

Induction

TauO



Model

- **Human** IPSCs including
  - **AD's** : Glu/GABA neurons (90/10% ratio)
- Tagged TauO in chamber **A** or **C**

Readouts

- Tagged oligomer trafficking
- Pathological phosphorylations
- Live staining
- Colocalization, internalization
- Aggregates

Tool

- High Content Screening and Analysis System with incubator for live staining (Time-lapse)

NETRI
PROVIDING ORGANS-ON-CHIP FOR THE INDUSTRY

ETAP-Lab
etap-lab.com

Neurodegeneration assay

Goal

Assessing the drug efficacy on neurodegeneration in BoC models of AD's induced by amyloid beta oligomers (AβO) and/or Tau oligomers (TauO).

Model

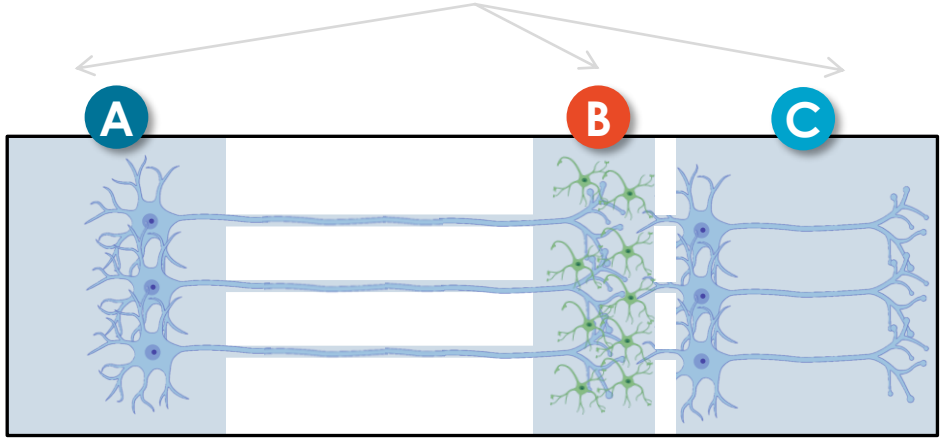
- **human IPSCs** (Glu/GABA neurons in a 90/10% ratio)
- AβO and/or TauO in chamber **A**, **B** or **C**

Readouts

- Synaptic & vesicular markers
- Autophagy, endocytosis, phagocytosis (microglia)
- Axonal & soma degeneration
- Morphological analysis
  - Dendritic spines
  - Neurite length
  - Network density
- Electrophysiology

Induction

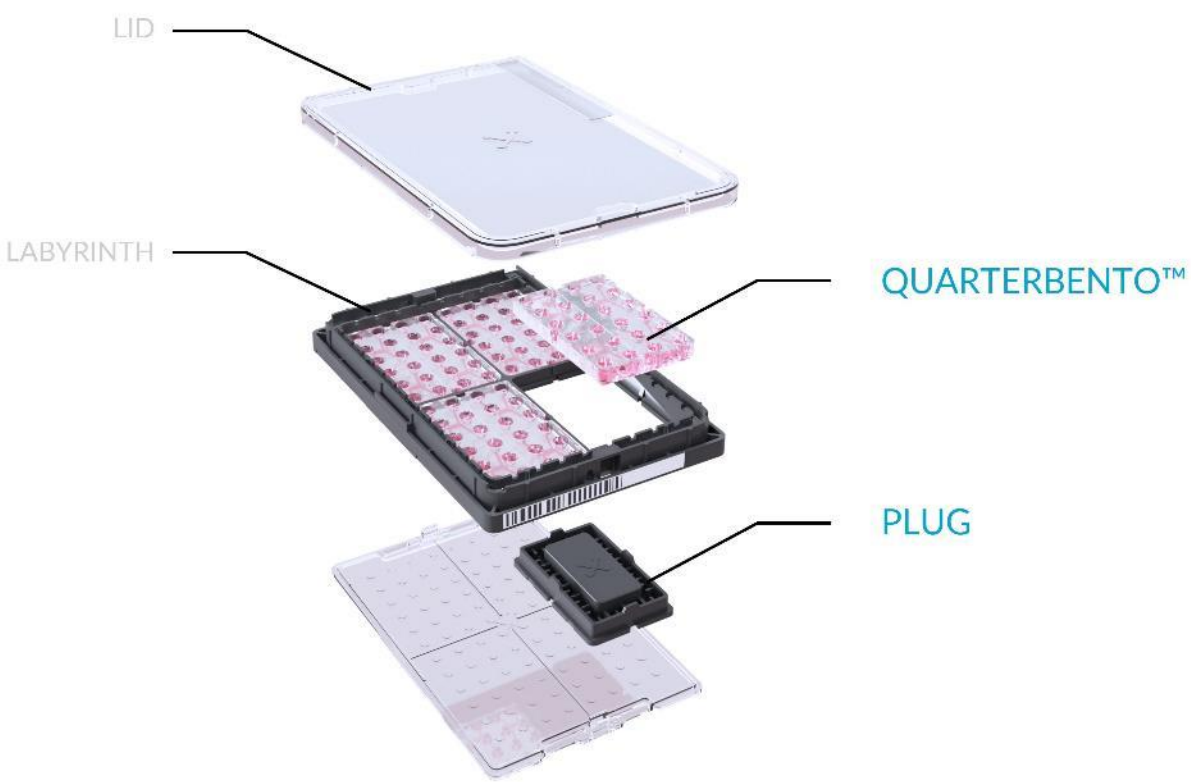
AβO and/or TauO



Tools

- Simple Plex assays (4 targets)
- High Content Screening and Analysis System
- Multielectrode array

Medium speed throughput



- ✓ 16 BoC per plate allowing replicates and multiple treatment comparisons
- ✓ Fast imaging process in living cells with Operetta CLS
- ✓ Results in 4-8 weeks after cell culture start
- ✓ Compartmentalization for more translational assays
- ✓ Need less chemicals and drugs than conventional in vitro assays

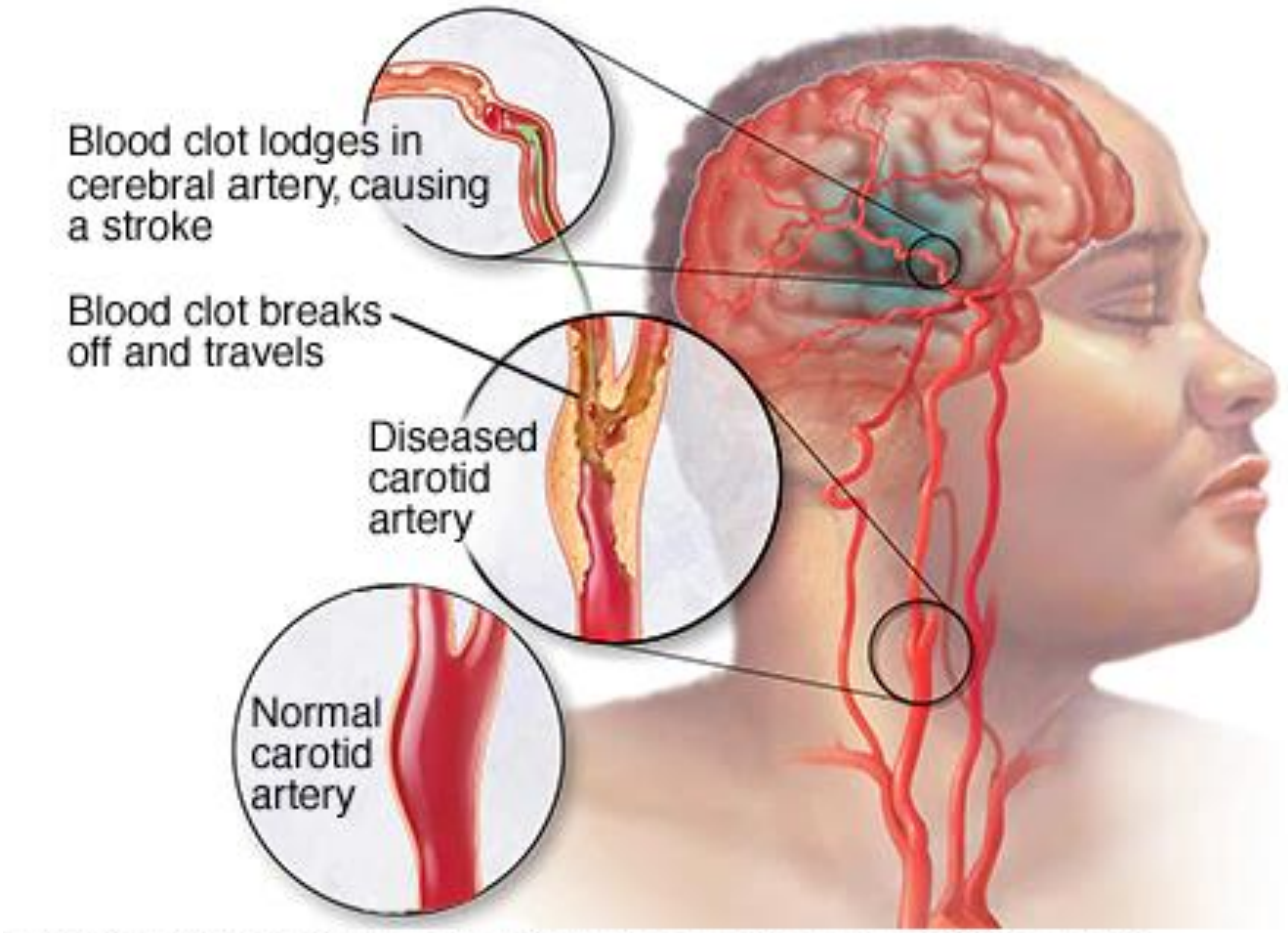
Alzheimer's disease

- **What is expected from these models?**
  - Support the understanding of the pathology
  - **<u>Expected better transnationality due to human cells + compartmentalization</u>**
  - Prerequisite to *in vivo* models for drug selection, reducing the number of animal studies
  - **<u>Excellent models for mechanistic studies</u>**

- **Potential pitfalls:**
  - The situation remain simplified (no BBB, no vessels, no CSF, no microglia, no myelin, growth factors, oxygenation, young cells in a stressing environment…)
  - How to validated cell phenotype compared to the human situation?
  - Pharmacological reference and comparators? Human variability?
  - Pathological concepts behind the models (amyloid hypothesis?)

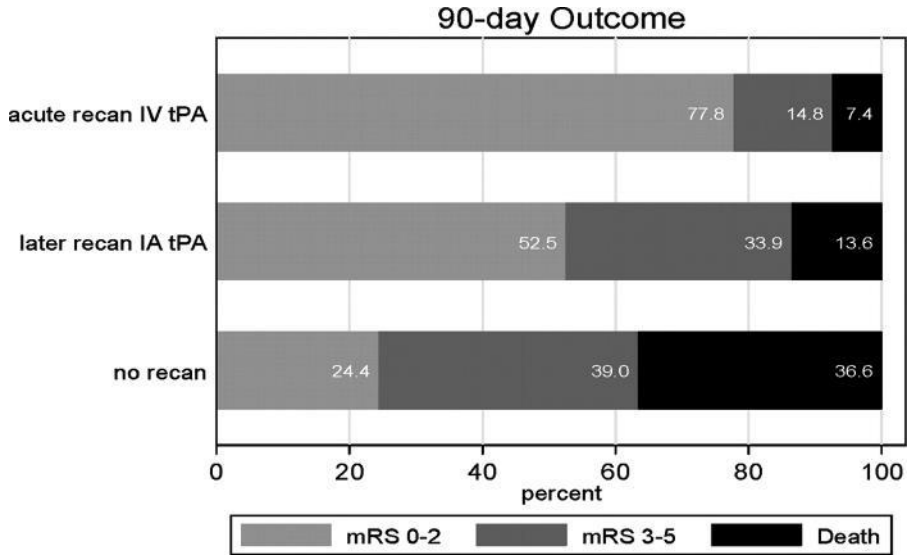
- **What will still be done in animals (even if successful)?**
  - PK/PD studies in a complete living system
  - Behavioral studies
  - Research of new mechanisms and biomarkers

Stroke models



Current treatments in stroke

- ❑ **The only effective strategy : early recanalization**
- ❑ **Two therapeutic options:**
  - ✓ **IV rt-PA (< 4.5h after stroke onset)**
    - *25% of patients treated*
  - ✓ **Thrombectomy (<6h after stroke onset)**
    - *<10% of patients treated*



From Bathia *et al.*. Stroke 2010

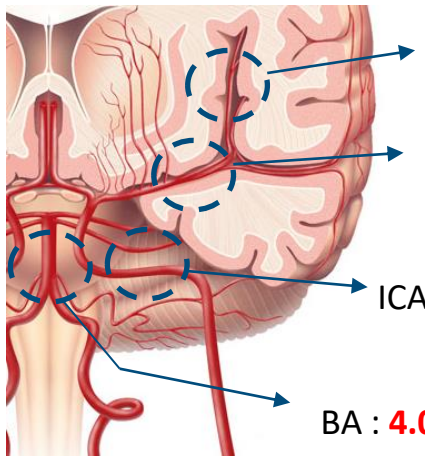
rt-PA (Alteplase, Actilyse) is the only approved drug for stroke

ETAP-Lab
etap-lab.com

rt-PA – the only drugs for acute stroke

- **Dose of 0.9 mg/kg (10% bolus; 90% perfusion over 1h) if <4.5h after stroke onset and DWI/PWI mismatch**
- **Full recanalization rate after i.v. thrombolysis: 21.3 %**

✓ **Recanalization rate depends on occlusion site**



MCA-M2 : **30.4 %**

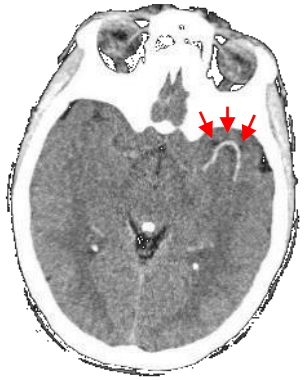
MCA-M1 : **32.8 %**

ICA : **4.4 %**

BA : **4.0 %**

From Bathia *et al.*, Stroke 2010

✓ **Recanalization rate depends on clot composition and length**



Low HU
Platelet-rich : → **5.9 %**

High HU
Erythrocyte and fibrin-rich : → **29.4 %**

Size
> 8 mm : → **0 %**

From Kim *et al.*, Neurology 2006

➡ **Recanalization mainly depends on thrombi location, length and composition**

ETAP-Lab
etap-lab.com

Why animal trials failed to select drugs?

- **Pitfall 1: brain differences**
  - Rodent have small, lissencephalic brains, with low white matter content
  - Human have large, gyrencephalic brains, with large white matter content
  - **Solution => use larger species than rodents**

- **Pitfall 2: outcomes are qualitatively different**
  - Preclinical studies rely on infarct size or cellular level measurements to evaluate therapeutic efficacy
  - Clinical trials rely on behavioral outcomes (neurologic state 90 days post stroke)
  - **Solution => focus on behavioral outcomes**

Why animal trials failed to select drugs?

- **Pitfall 3: outcomes at early times are not reliable in humans**
  - Preclinical studies have relied on early outcomes
  - Whereas clinical trials rely on late assessments (neurologic state 90 days post stroke)
  - **Solution : increase duration of recovery follow-up**

- **Pitfall 4: experimental models are homogeneous, human stroke is heterogeneous**
  - rt-PA induce 100% recanalization rate in models => homogeneity and control
  - rt-PA induce 20% full recanalization rate in humans => clot locations, constitution, duration, genetic variability, sex, age,…
  - **Solution: increasing variability and group size**

ETAP-Lab
etap-lab.com

Why animal trials failed to select drugs?

- **Pitfall 5: comorbidities**
  - Animals are young healthy males
  - Human patients are aged, with comorbidities, with sex differences
  - **Solution: use aged animals with comorbidities in both sexes**

- **Pitfall 6: therapeutic window**
  - Animals are usually treated at early time to maximize drug effect in small groups
  - Humans are often treated lately (up to 4.5h post-stroke for rt-PA), effect decreasing with time
  - **Solution: relevant treatment scheme according to mechanism of action**

ETAP-Lab
etap-lab.com

What about NAM for stroke studies?

- Must of the identified pitfalls cannot be avoided by NAMs
- Currently, no *in vitro* system can reproduce the complex interaction between all the systems involved in stroke:
  - Blood and functional arteries
  - BBB
  - Neurons + all glial cells
  - Plexus choroids and CSF flow
  - Functional immune system
  - Brain plasticity
  - …
- New innovative animal models seems to present increased translational values

ETAP-Lab
etap-lab.com

Conclusion

- We are at the very beginning of a long process to replace animals in the field of complex neurologic diseases
- NAMs such as OoC or organoids are very promising tools to study neurodegenerative diseases
- NAMs may present better translational value than animal models while allowing to strongly reduce their use in the field
- Uyltimately, NAMs may not be able to fully replace animal models in neurology, especially for pathologies were size and/or complexity matter (e.g. stroke) or with poorly understood etiology (e.g. schizophrenia)
